#### Abstract

We investigate MEBDF methods of Cash from general linear methods point of view. Some Perturbations of these methods are constructed which preserve the order of these formulas and improve their stability properties.

Key words: MEBDF methods, general linear methods, stability analysis, A-stability,  $A(\alpha)$ -stability.

## 1. Introduction

To improve stability properties of backward differentiation formulas (BDFs) for ordinary differential equations (ODEs)

$$\begin{cases} y'(t) = f(t, y(t)), & t \in [t_0, T], \\ y(t_0) = y_0 \in \mathbb{R}^m, \end{cases}$$
(1.1)

Cash [1] proposed the extension of these methods which utilizes a future point at  $t_{n+k+1}$ . These extended BDF (EBDF) methods take the form

$$\sum_{j=0}^{k} \alpha_j y_{n+j} = h \beta_k f_{n+k} + h \beta_{k+1} f_{n+k+1}, \qquad (1.2)$$

where  $f_{n+k} = f(t_{n+k}, y_{n+k})$ ,  $f_{n+k+1} = f(t_{n+k+1}, y_{n+k+1})$ . The coefficients  $\alpha_j$ , j = 0, 1, ..., k,  $\beta_k$ ,  $\beta_{k+1}$ , of these methods are computed by solving the appropriate order conditions for the order p = k + 1 and with the normalization  $\alpha_k = 1$ . These coefficients are listed in [1] for k = 1, 2, ..., 8. The resulting methods are *A*- and *L*-stable for k = 1, 2, and 3, and  $A(\alpha)$ -stable for k = 4, 5, 6, 7, and 8. The regions of absolute stability of these methods are plotted in [1] and [7].

Assuming that the approximations  $y_n, y_{n+1}, \ldots, y_{n+k-1}$  to the solution y of (1.1) at the points  $t_n, t_{n+1}, \ldots, t_{n+k-1}$  are already computed the algorithm based on EBDF methods is defined by the following three steps: (i) Compute  $\overline{y}_{n+k}$  as the solution of the conventional BDF method

$$\overline{y}_{n+k} + \sum_{j=0}^{k-1} \widehat{\alpha}_j y_{n+j} = h \widehat{\beta}_k \overline{f}_{n+k}, \qquad (1.3)$$

 $\overline{f}_{n+k} = f(t_{n+k}, \overline{y}_{n+k}).$ 

(ii) Compute  $\bar{y}_{n+k+1}$  as the solution of the same BDF advanced one step, that is,

$$\overline{y}_{n+k+1} + \widehat{\alpha}_{k-1}\overline{y}_{n+k} + \sum_{j=0}^{k-2} \widehat{\alpha}_j y_{n+j+1} = h \widehat{\beta}_k \overline{f}_{n+k+1}, \qquad (1.4)$$

 $\overline{f}_{n+k+1} = f(t_{n+k+1}, \overline{y}_{n+k+1}).$ 

(iii) Discard  $\overline{y}_{n+k}$ , insert  $\overline{f}_{n+k+1}$  into EBDF method (1.2), and solve for  $y_{n+k}$ :

$$y_{n+k} + \sum_{j=0}^{k-1} \alpha_j y_{n+j} = h\beta_k f_{n+k} + h\beta_{k+1} \overline{f}_{n+k+1}.$$
 (1.5)

November 15, 2011

The coefficients  $\widehat{\alpha}_j$ , j = 0, 1, ..., k,  $\widehat{\alpha}_k = 1$ ,  $\widehat{\beta}_k$ , of BDF methods are listed in [11] for k = 1, 2, ..., 6 and in [1] for k = 7 and 8. If the EBDF method (1.2) is of order k + 1 and BDF methods (1.3) and (1.4) are of order k, then the overall algorithm (i)-(iii) based on (1.3), (1.4), and (1.5) is of order k + 1 [1].

It was observed by Cash [2] and Hairer and Wanner [8] that the disadvantage of the algorithm given above is that stages (i) and (ii) represent nonlinear systems with the same Jacobian  $I - h\beta_k J$ ,  $J = \partial f / \partial y$ , but stage (iii) has a different Jacobian,  $I - h\beta_k J$ , which requires extra LU decomposition. To remedy this situation, Cash [2] proposed an algorithm where the last stage (iii) was replaced by a modified EBDF (MEBDF) method of the form

$$\sum_{j=0}^{k} \alpha_{j} y_{n+j} = h \widehat{\beta}_{k} f_{n+k} + h (\beta_{k} - \widehat{\beta}_{k}) \overline{f}_{n+k} + h \beta_{k+1} \overline{f}_{n+k+1}.$$
(1.6)

These methods have order k + 1 and are also A- and L-stable for  $k = 1, 2, and 3, and A(\alpha)$ -stable for k = 4, 5, 6, 7, 1and 8 with larger angles  $\alpha$  than that of the corresponding EBDF methods. These angles for BDF, EBDF, and MEBDF methods are listed in [1, 2, 7, 8] and reproduced also in [10]. The stability regions of MEBDF methods (1.6) have been plotted in [8].

In Section 2 the MEBDF methods will be reformulated as general linear methods (GLMs) for ODEs. In Section 3 we propose a perturbation of MEDBF methods which will preserve their order and improve their stability properties. In Section 4 we provide examples of perturbed MEBDF methods for k = 4, 5, 6, 7, and 8. In Section 5 we discuss local error estimation for small and large stepsizes. Finally, in Section 6 some concluding remarks are given and plans for future research are briefly discussed.

### 2. MEBDF methods as GLMs

GLMs for the numerical solution of ODEs (1.1) are defined by

$$\begin{cases} Y_i^{[n]} = h \sum_{j=1}^{s} a_{ij} f(Y_j^{[n]}) + \sum_{j=1}^{r} u_{ij} y_j^{[n-1]}, & i = 1, 2, \dots, s, \\ y_i^{[n]} = h \sum_{j=1}^{s} b_{ij} f(Y_j^{[n]}) + \sum_{j=1}^{r} v_{ij} y_j^{[n-1]}, & i = 1, 2, \dots, r, \end{cases}$$

$$(2.1)$$

n = 1, 2, ..., N, where  $Nh = T - t_0$ . Here, the internal stages  $Y_i^{[n]}$  are approximations of stage order q to  $y(t_{n-1} + c_ih)$ , and the external stages  $y_i^{[n]}$  are approximations of order p to the linear combinations of scaled derivatives of y(t) in  $t = t_n$ , compare [10]. These methods are specified by the abscissa vector  $\mathbf{c} = [c_1, \dots, c_s]^T$  and the coefficient matrices

$$\mathbf{A} \in \mathbb{R}^{s \times s}, \quad \mathbf{U} \in \mathbb{R}^{s \times r}, \quad \mathbf{B} \in \mathbb{R}^{r \times s}, \quad \mathbf{V} \in \mathbb{R}^{r \times r}.$$

Putting

$$Y^{[n]} = \begin{bmatrix} Y_1^{[n]} \\ \vdots \\ Y_s^{[n]} \end{bmatrix}, \quad hf(Y^{[n]}) = \begin{bmatrix} hf(Y_1^{[n]}) \\ \vdots \\ hf(Y_s^{[n]}) \end{bmatrix}, \quad y^{[n]} = \begin{bmatrix} y_1^{[n]} \\ \vdots \\ y_r^{[n]} \end{bmatrix},$$

the GLM (2.1) can be written in vector form as follows

$$\begin{bmatrix} Y^{[n]} \\ \hline y^{[n]} \end{bmatrix} = \begin{bmatrix} \mathbf{A} \otimes \mathbf{I} & \mathbf{U} \otimes \mathbf{I} \\ \hline \mathbf{B} \otimes \mathbf{I} & \mathbf{V} \otimes \mathbf{I} \end{bmatrix} \begin{bmatrix} hf(Y^{[n]}) \\ \hline y^{[n-1]} \end{bmatrix},$$
(2.2)

 $n = 1, 2, \dots, N$ . Here, I is the identity matrix of dimension m and ' $\otimes$ ' stands for Kronecker product of matrices. Substituting (1.3) into (1.4), we obtain

$$\overline{y}_{n+k+1} = \widehat{\alpha}_{k-1}\widehat{\alpha}_0 y_n + \sum_{j=1}^{k-1} (\widehat{\alpha}_{k-1}\widehat{\alpha}_j - \widehat{\alpha}_{j-1})y_{n+j} - h\widehat{\alpha}_{k-1}\widehat{\beta}_k\overline{f}_{n+k} + h\widehat{\beta}_k\overline{f}_{n+k+1}.$$
(2.3)

Then it can be verified that an algorithm based on formulas (1.3), (2.3), and (1.6) can be written as a GLM of the form (2.2) with s = 3, r = k, and with the vectors of internal approximations  $Y^{[n]}$ ,  $f(Y^{[n]})$ , and the vector of external approximations  $y^{[n]}$  defined by

г

$$Y^{[n]} = \begin{bmatrix} \overline{y}_{n+k} \\ \overline{y}_{n+k+1} \\ y_{n+k} \end{bmatrix}, \quad f(Y^{[n]}) = \begin{bmatrix} \overline{f}_{n+k} \\ \overline{f}_{n+k+1} \\ f_{n+k} \end{bmatrix}, \quad y^{[n]} = \begin{bmatrix} y_{n+k} \\ y_{n+k-1} \\ \vdots \\ y_{n+1} \end{bmatrix},$$

and with the coefficient matrices A, U, B, and V given by

$$\mathbf{A} = \begin{bmatrix} \widehat{\beta}_{k} & 0 & 0 \\ -\widehat{\alpha}_{k-1}\widehat{\beta}_{k} & \widehat{\beta}_{k} & 0 \\ \beta_{k} - \widehat{\beta}_{k} & \beta_{k+1} & \widehat{\beta}_{k} \end{bmatrix},$$
$$\mathbf{U} = \begin{bmatrix} -\widehat{\alpha}_{k-1} & -\widehat{\alpha}_{k-2} & \cdots & -\widehat{\alpha}_{1} & -\widehat{\alpha}_{0} \\ \widehat{\alpha}_{k-1}\widehat{\alpha}_{k-1} - \widehat{\alpha}_{k-2} & \widehat{\alpha}_{k-1}\widehat{\alpha}_{k-2} - \widehat{\alpha}_{k-3} & \cdots & \widehat{\alpha}_{k-1}\widehat{\alpha}_{1} - \widehat{\alpha}_{0} & \widehat{\alpha}_{k-1}\widehat{\alpha}_{0} \\ -\alpha_{k-1} & -\alpha_{k-2} & \cdots & -\alpha_{1} & -\alpha_{0} \end{bmatrix},$$
$$\mathbf{B} = \begin{bmatrix} \beta_{k} - \widehat{\beta}_{k} & \beta_{k+1} & \widehat{\beta}_{k} \\ 0 & 0 & 0 \\ \vdots & \vdots & \vdots \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \quad \mathbf{V} = \begin{bmatrix} -\alpha_{k-1} & -\alpha_{k-2} & \cdots & -\alpha_{1} & -\alpha_{0} \\ 1 & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & 1 & 0 \end{bmatrix}.$$

We have

$$\mathbf{A} \in \mathbb{R}^{3 \times 3}, \quad \mathbf{U} \in \mathbb{R}^{3 \times k}, \quad \mathbf{B} \in \mathbb{R}^{k \times 3}, \quad \mathbf{V} \in \mathbb{R}^{k \times k}.$$

## 3. Perturbed and fully perturbed MEBDF methods

Observe that for the algorithm based on MEBDF methods written as GLMs we have

$$Y_3^{[n]} = y_1^{[n]},$$

and

$$y_i^{[n]} = y_{i-1}^{[n-1]}, \quad i = 2, 3, \dots, k.$$

We now consider the perturbation of these methods, where the coefficient matrix **B**, which will be denoted by the same symbol, takes the form

$$\mathbf{B} = \begin{bmatrix} \beta_k - \widehat{\beta}_k + b_{11} & \beta_{k+1} + b_{12} & \widehat{\beta}_k + b_{13} \\ b_{21} & b_{22} & b_{23} \\ \vdots & \vdots & \vdots \\ b_{k-1,1} & b_{k-1,2} & b_{k-1,3} \\ b_{k,1} & b_{k,2} & b_{k,3} \end{bmatrix},$$

and we choose the coefficients  $b_{ij}$  in such a way that the order of the underlying MEBDF method is preserved, i.e.

$$Y_3^{[n]} = y_1^{[n]} + O(h^{p+1}), (3.1)$$

$$y_i^{[n]} = y_{i-1}^{[n-1]} + O(h^{p+1}), \quad i = 2, 3, \dots, k,$$
(3.2)

where p = k + 1 is the order of MEBDF methods. Since

$$\begin{split} Y_{3}^{[n]} &= -\sum_{j=0}^{k-1} \alpha_{j} y_{k-j}^{[n-1]} + (\beta_{k} - \widehat{\beta}_{k}) h \overline{f}_{n+k} + \beta_{k+1} h \overline{f}_{n+k+1} + \widehat{\beta}_{k} h f_{n+k}, \\ y_{1}^{[n]} &= -\sum_{j=0}^{k-1} \alpha_{j} y_{k-j}^{[n-1]} + (\beta_{k} - \widehat{\beta}_{k} + b_{11}) h \overline{f}_{n+k} + (\beta_{k+1} + b_{12}) h \overline{f}_{n+k+1} + (\widehat{\beta}_{k} + b_{13}) h f_{n+k} \\ y_{i}^{[n]} &= y_{i-1}^{[n-1]} + b_{i1} h \overline{f}_{n+k} + b_{i2} h \overline{f}_{n+k+1} + b_{i3} h f_{n+k}, \quad 2 \le i \le k, \end{split}$$

and

$$h\overline{f}_{n+k} = hy'(t_{n+k}) + O(h^{p+1}), \quad h\overline{f}_{n+k+1} = hy'(t_{n+k+1}) + O(h^{p+1}), \quad hf_{n+k} = hy'(t_{n+k}) + O(h^{p+1}),$$

this leads to

$$b_{i1} = b_i$$
,  $b_{i2} = 0$ ,  $b_{i3} = -b_i$ ,  $i = 1, 2, \dots, k$ 

where  $b_i$  are arbitrary parameters. Hence, the resulting coefficient matrix **B** takes the form

	$\beta_k - \widehat{\beta}_k + b_1$	$\beta_{k+1}$	$\widehat{\beta}_k - b_1$	
	$b_2$	0	$-b_{2}$	
<b>B</b> =	÷	÷	÷	
	$b_{k-1}$	0	$-b_{k-1}$	
	$b_k$	0	$-b_k$	

To preserve the FSAL property (first same as last, compare [13]) of the MEBDF, we will distinguish two different cases for which  $b_1 = 0$  and  $b_1 \neq 0$ , respectively. These methods will be called perturbed MEBDF (PMEBDF) and fully perturbed MEBDF (FPMEBDF), respectively. It follows from (3.1) and (3.2) that PMEBDF and FPMEBDF methods have the same order as the underlying MEBDF methods for any  $b_i$ , i = 1, 2, ..., k. These free parameters will then be chosen to maximize the angle  $\alpha$  of  $A(\alpha)$ -stability. To accomplish this goal, using the boundary locus technique [11], we have written an objective function f which approximates the value of the angle  $\alpha$  specific choices of parameters  $b_i$ , i = 1, 2, ..., k. This objective function was then minimized using the function fminsearch from Matlab. In this search we started with initial values  $b_i = 0$ , i = 1, 2, ..., k, which correspond to MEBDF methods, as well as with random initial values from the interval [-3, 3]. The examples of methods obtained in this way and their respective stability domains are presented in Section 4.

## 4. Examples of PMEBDF and FPMEBDF methods

Since the MEBDF methods corresponding to k = 1, 2, and 3 are already A- and L-stable we performed our search for k = 4, 5, 6, 7, and 8. The values of the coefficients are expressed in rational form; such rational approximations have been provided by using Matlab rats function, with default accuracy  $10^{-6}$ .

For k = 4 an example of PMEBDF method with large region of  $A(\alpha)$ -stability is given by

$$b_1 = 0$$
,  $b_2 = -\frac{337}{374}$ ,  $b_3 = -\frac{982}{207}$ ,  $b_4 = -\frac{1365}{137}$ 

This method is  $A(\alpha)$ -stable for  $\alpha = 89.32$ . An example of FPMEBDF method with k = 4 is given by

$$b_1 = -\frac{432}{199}, \quad b_2 = -\frac{2181}{206}, \quad b_3 = -\frac{1821}{71}, \quad b_4 = -\frac{4099}{93},$$

and

Figure 4.1: Regions of stability of PEMBDF method (thin line), FPMBDF method (medium line) and MEBDF method (thick line) for k = 4

$\alpha$ for FPMEBDF	90°	90°	90°	<b>89.7</b> 1°	88.01°	84.67°	78.70°	65.01°

Table 4.1: Angles  $\alpha$  of  $A(\alpha)$ -stability for BDF, EBDF, MEBDF, and PMEBDF formulas for k = 1, 2, ..., 8

whose angle of  $A(\alpha)$ -stability is for  $\alpha = 89.71$ . The region of stability of the PMEBDF method is plotted by a thin line in Fig. 4.1 and the one of the FPMEBDF is plotted by a medium line, together with a region of stability of the corresponding MEBDF method, which is plotted by a thick line.

For k = 5 an example of PMEBDF method with large region of  $A(\alpha)$ -stability is given by

$$b_1 = 0$$
,  $b_2 = -\frac{264}{281}$ ,  $b_3 = -\frac{16329}{4082}$ ,  $b_4 = -\frac{1399}{165}$ ,  $b_5 = -\frac{3002}{187}$ 

This method is  $A(\alpha)$ -stable for  $\alpha = 86.19$ . An example of FPMEBDF method with k = 5 is given by

$$b_1 = -\frac{96}{47}, \quad b_2 = -\frac{1411}{135}, \quad b_3 = -\frac{8367}{298}, \quad b_4 = -\frac{7914}{137}, \quad b_5 = -\frac{3817}{36},$$

whose angle of  $A(\alpha)$ -stability is for  $\alpha = 88.01$ . The corresponding stability regions are plotted in Fig. 4.2.

For k = 6 an example of PMEBDF method with large region of  $A(\alpha)$ -stability is given by

$$b_1 = 0$$
,  $b_2 = -\frac{319}{305}$ ,  $b_3 = -\frac{236}{71}$ ,  $b_4 = -\frac{2220}{437}$ ,  $b_5 = -\frac{570}{161}$ ,  $b_6 = \frac{728}{75}$ 

This method is  $A(\alpha)$ -stable for  $\alpha = 80.60$ . An example of FPMEBDF method with k = 6 is given by

$$b_1 = -\frac{92}{63}, \quad b_2 = -\frac{652}{103}, \quad b_3 = -\frac{707}{58}, \quad b_4 = -\frac{389}{42}, \quad b_5 = \frac{2029}{81}, \quad b_6 = \frac{3155}{23},$$

whose angle of  $A(\alpha)$ -stability is for  $\alpha = 84.67$ . The corresponding stability regions are plotted in Fig. 4.3.

For k = 7 an example of PMEBDF method with large region of  $A(\alpha)$ -stability is given by

$$b_1 = 0, \quad b_2 = -\frac{199}{304}, \quad b_3 = -\frac{30}{19},$$

Figure 4.2: Regions of stability of PEMBDF method (thin line), FPMBDF method (medium line) and MEBDF method (thick line) for k = 5

Figure 4.3: Regions of stability of PEMBDF method (thin line), FPMBDF method (medium line) and MEBDF method (thick line) for k = 6

$$b_4 = -\frac{690}{427}, \quad b_5 = -\frac{259}{760}, \quad b_6 = \frac{665}{383}, \quad b_7 = -\frac{317}{153}$$

This method is  $A(\alpha)$ -stable for  $\alpha = 72.63$ . An example of FPMEBDF method with k = 7 is given by

$$b_1 = -\frac{50}{49}, \quad b_2 = -\frac{1063}{259}, \quad b_3 = -\frac{695}{92},$$
  
 $b_4 = -\frac{959}{130}, \quad b_5 = -\frac{169}{214}, \quad b_6 = \frac{472}{123}, \quad b_7 = -\frac{3590}{101}$ 

whose angle of  $A(\alpha)$ -stability is for  $\alpha = 78.70$ . The corresponding stability regions are plotted in Fig. 4.4. For k = 8 an example of PMEBDF method with large region of  $A(\alpha)$ -stability is given by

$$b_1 = 0, \quad b_2 = -\frac{25}{163}, \quad b_3 = \frac{3}{763}, \quad b_4 = \frac{447}{880},$$
  
 $b_5 = \frac{111}{166}, \quad b_6 = \frac{371}{729}, \quad b_7 = -\frac{5}{401}, \quad b_8 = -\frac{17}{21}.$ 

This method is  $A(\alpha)$ -stable for  $\alpha = 60.60$ . An example of FPMEBDF method with k = 8 is given by

$$b_1 = -\frac{337}{783}, \quad b_2 = -\frac{382}{225}, \quad b_3 = -\frac{921}{314}, \quad b_4 = -\frac{1013}{377},$$
  
 $b_5 = -\frac{35}{188}, \quad b_6 = \frac{1172}{349}, \quad b_7 = \frac{1099}{268}, \quad b_8 = -\frac{359}{672}.$ 

whose angle of  $A(\alpha)$ -stability is for  $\alpha = 65.01$ . The corresponding stability regions are plotted in Fig. 4.5.

Figure 4.4: Regions of stability of PEMBDF method (thin line), FPMBDF method (medium line) and MEBDF method (thick line) for k = 7

These angles  $\alpha$  of  $A(\alpha)$ -stability for PEMBDF methods are presented in Table 4.1 together with the corresponding angles for BDF, EBDF, and MBDF formulas. The asterisk in this table indicates that the method is not  $A(\alpha)$ -stable. As it can be noticed from the results reported in Table 4.1, an improvement in the angles of  $A(\alpha)$ -stability is visible for perturbed and fully perturbed formulae with respect to MEBDF methods. In particular, the more *k* increases, the more the angle improvement is remarkable.

Figure 4.5: Regions of stability of PEMBDF method (thin line), FPMBDF method (medium line) and MEBDF method (thick line) for k = 8

In order to provide a numerical confirmation of the theoretical expectations regarding the improvement achieved in the angles of  $A(\alpha)$ -stability, we consider the following test problem

$$y' = Ay, \quad t \in [0, 50],$$
 (4.1)

with

$$A = \begin{bmatrix} -a & -b \\ b & -a \end{bmatrix}, \ a > 0, \ b > 0,$$

for which  $\sigma(A) = \{-a + bi, -a - bi\}$ . We compared the perturbed and fully perturbed formulae with k = 8, with the MEBDF methods in a fixed stepsize environment with stepsize  $h = h_1, h_2$ , where  $h_1 = 0.05$  and  $h_2 = 0.1$ . For  $h = h_1$ , the points  $h(-10 \pm 15i)$  are inside of stability regions for all methods and the numerical approximations tend to 0 as the numerical solution advances. For  $h = h_2$  the points  $h(-10 \pm 15i)$  are outside of stability regions for MEBDF methods and inside of stability region for PMEBDF and FPMEBDF methods. We have confirmed numerically that in this case the numerical approximation computed by MEBDF method is divergent, where those computed by PMEBDF and FPEMBDF formulas tend to zero as the numerical solution advances. We repeated the numerical tests also in the cases k = 6 and k = 7, choosing respectively a = 5, b = 25 and a = 10, b = 25. The results of such computation are

listed in Table 4.2, where the absolute error  $E_N = ||y(T) - y_N||_1$ , N = hT, is reported. The related points h(-a + b i), for  $h = h_1$  and  $h = h_2$  are plotted on Fig. 4.6, Fig. 4.7 and Fig. 4.8.

h	a	b	k	MEBDF	PMEBDF	FPMEBDF

Figure 4.7: Stability regions near origin of MEBDF, PMEBDF, FPMEBDF methods corresponding to k = 7 and the points  $h_1(-10 + 25i)$ ,  $h_2(-10 + 25i)$ , where  $h_1 = 0.05$  and  $h_2 = 0.1$ .

## 5. Local error estimation

This section is devoted to the derivation of a reliable estimation to principal term of the local truncation error  $h^p y^{(p+1)}(t_n)$ . In order to accomplish this purpose, some preliminary considerations are needed.

Figure 4.8: Stability regions near origin of MEBDF, PMEBDF, FPMEBDF methods corresponding to k = 8 and the points  $h_1(-10 + 15i)$ ,  $h_2(-10 + 15i)$ , where  $h_1 = 0.05$  and  $h_2 = 0.1$ .

Let us consider the local solution  $\tilde{y}(t)$ , i.e. the solution to the initial-value problem

$$\begin{cases} \widetilde{y}'(t) = f(\widetilde{y}(t)), & t \in [t_n, t_{n+1}], \\ \widetilde{y}(t_n) = y_n, \end{cases}$$
(5.1)

where the function f(y) appearing in (1.1) and (5.1) satisfies the Lipschitz condition of the form

$$||f(y) - f(z)|| \le L||y - z||,$$

with a constant  $L \ge 0$ . Subtracting the integral forms of (1.1) and (5.1) we obtain

$$||y(t) - \widetilde{y}(t)|| \le ||y(t_n) - y_n|| + L \int_{t_n}^t ||y(s) - \widetilde{y}(s)|| ds,$$

 $t \in [t_n, t_{n+1}]$ . Using Gronwall's lemma (compare for example [13]) yields

$$||y(t) - \widetilde{y}(t)|| \le ||y(t_n) - y_n||e^{L(t-t_n)}$$

Hence,

$$||y(t) - \widetilde{y}(t)|| = O(h^p), \quad t \in [t_n, t_{n+1}].$$

Assuming that the function f(y) is sufficiently smooth we have similar conclusion for the derivatives of y(t) and  $\tilde{y}(t)$ 

$$\|y^{(i)}(t) - \widetilde{y}^{(i)}(t)\| = O(h^p), \quad t \in [t_n, t_{n+1}], \quad i = 1, 2, \dots,$$

compare [12].

In this section we aim to provide an estimation to the leading term of the local truncation error having the form

$$h^{p+1}\tilde{y}^{(p+1)}(t_n) \approx \sum_{j=0}^k \sigma_j y_{n+j} + \sigma_{k+1} h \overline{f}_{n+k} + \sigma_{k+2} h \overline{f}_{n+k+1}.$$
 (5.2)

The following result holds.

**Theorem 5.1.** Assume that the solution  $\tilde{y}(t)$  to the problem (5.1) is sufficiently smooth. Then the constants  $\sigma_0, \sigma_1, \ldots, \sigma_{k+2}$  appearing in (5.2) satisfy the following linear system of equations

$$\begin{cases} \sum_{j=0}^{k} \sigma_{j} = 0, \\ \sum_{j=0}^{k} \sigma_{j} \frac{j^{\ell}}{\ell!} + \sigma_{k+1} \frac{k^{\ell-1}}{(\ell-1)!} + \sigma_{k+2} \frac{(k+1)^{\ell-1}}{(\ell-1)!} = 0, \qquad \ell = 1, 2, \dots, p, \end{cases}$$
(5.3)  
$$\sum_{j=0}^{k} \sigma_{j} \frac{j^{p+1}}{(p+1)!} + \sigma_{k+1} \frac{k^{p}}{p!} + \sigma_{k+2} \frac{(k+1)^{p}}{p!} = 1.$$

*Proof*: Under the localizing assumption, it is  $\tilde{y}_{n+j} = \tilde{y}(t_{n+j})$ , j = 0, 1, ..., k - 1. Expanding  $\tilde{y}(t_n + jh)$  and  $\tilde{y}'(t_n + jh)$  in Taylor series around  $t_n$ , leads to

$$\widetilde{y}(t_n + jh) = \sum_{\ell=0}^{p} \frac{(jh)^{\ell}}{\ell!} \widetilde{y}^{(\ell)}(t_n) + O(h^{p+1}), \quad \widetilde{y}'(t_n + jh) = \sum_{\ell=1}^{p} \frac{(jh)^{\ell-1}}{(\ell-1)!} \widetilde{y}^{(\ell)}(t_n) + O(h^{p+1}).$$

Substituting these relations in (5.2) we obtain

$$h^{p+1}\widetilde{y}^{(p+1)}(t_n) = \sum_{j=0}^k \sigma_j \widetilde{y}(t_n) + \sum_{\ell=1}^{p+1} \left( \sum_{j=0}^k \sigma_j \frac{j^\ell}{\ell!} + \sigma_{k+1} \frac{k^{\ell-1}}{(\ell-1)!} + \sigma_{k+2} \frac{(k+1)^{\ell-1}}{(\ell-1)!} \right) h^\ell \widetilde{y}^{(\ell)}(t_n) + O(h^{p+2}).$$

Comparing the terms of order  $O(h^k)$  for k = 0, 1, ..., p + 1 yields the system (5.3).

We observe that system (5.3) can be written in a more compact vector form, as follows:

$$K\sigma = e_{k+3},$$

where the coefficient matrix K assumes the form

$$\begin{bmatrix} 1 & 1 & \dots & 1 & \dots & 0 & 0 \\ 0 & 1 & \dots & j & \dots & 1 & 1 \\ \vdots & \vdots & \ddots & \vdots & & \vdots & \vdots \\ 0 & 1 & \dots & \frac{j^{\ell}}{\ell!} & \dots & \frac{k^{\ell-1}}{(\ell-1)!} & \frac{(k+1)^{\ell-1}}{(\ell-1)!} \\ \vdots & \vdots & & \vdots & \ddots & \vdots & \vdots \\ 0 & 1 & \dots & \frac{j^{p}}{p!} & \dots & \frac{k^{p-1}}{(p-1)!} & \frac{(k+1)^{p-1}}{(p-1)!} \\ 0 & 1 & \dots & \frac{j^{p+1}}{(p+1)!} & \dots & \frac{k^{p}}{p!} & \frac{(k+1)^{p}}{p!} \end{bmatrix} \in \mathbb{R}^{(p+2)\times(k+3)},$$

 $\sigma = [\sigma_0, \sigma_1, \dots, \sigma_{k+2}]^T$  and  $e_{k+3}$  is the (k+3)-rd vector of the standard basis of  $\mathbb{R}^{k+3}$ . We observe that, even if the matrix *K* is not the Vandermonde matrix, its non-singularity can be proved with arguments analogous to the ones used for the Vandermonde matrix (similar analysis have been carried out, for instance, in [5]). In particular, it can be proved that, if p = k + 1, the system (5.3) has a unique solution for any value of *k*. These unique solutions to the system (5.3) for different values of *k* are listed below:

• k = 1:  $\sigma = \begin{bmatrix} -\frac{12}{5} & \frac{12}{5} & -\frac{18}{5} & \frac{6}{5} \end{bmatrix}^T$ • k = 2:  $\sigma = \begin{bmatrix} \frac{30}{17} & -\frac{168}{17} & \frac{138}{17} & -\frac{132}{17} & \frac{24}{17} \end{bmatrix}^T$ 

We have provided the estimation (5.2) to the local truncation error, which is asymptotically correct for *h* tending to 0. However, in order to approach stiff systems, this property of correctness is not sufficient, since their solution also requires the usage of large stepsizes with respect to certain features of the problem. Shampine and Baca in [14] focused their attention on the assessment of the quality of the error estimate for large values of the stepsize, by using similar arguments as in the classical theory of absolute stability. We now specialize the results obtained in [14] to our class of PMEBDF methods.

Following [14], we consider a restricted class of problems of the form y' = Jy, where J is a constant matrix that can be diagonalized by a similarity transformation  $M^{-1}JM = \text{diag}(\xi_i)$ . Then, it is sufficient to consider the scalar problem

$$\begin{cases} y'(t) = \xi y, & t \ge 0, \\ y(0) = 1, \end{cases}$$
(5.4)

where  $\xi \in \mathbb{C}$  is one the eigenvalues of *J*, which is supposed to have negative real part. The solution of the problem (5.4) is  $y(t) = e^{\xi t}$  and, therefore,

$$y_{n+i} = e^{\xi(t_n+jh)} + O(h^{p+1}).$$

As a consequence, we obtain

$$le(t_n) = e^{\xi t_n} \left( \sum_{j=0}^k \alpha_j e^{jz} - z\beta_k e^{kz} - z\beta_{k+1} e^{(k+1)z} \right) + O(z^{p+1}),$$

where  $z = \xi h$ . Using the results contained in Theorem 5.1, we next provide the estimate (5.2) est( $t_n$ ), obtaining

$$\operatorname{est}(t_n) = C_p(t_n) e^{\xi t_n} \left( \sum_{j=0}^k \sigma_j e^{jz} + z \sigma_{k+1} e^{kz} - z \sigma_{k+2} e^{(k+1)z} \right) + O(z^{p+1}).$$

To investigate the behaviour of error estimates for large values of z, we define the functions  $R_{le}(z)$  and  $R_{est}(z)$  by

$$R_{\rm le}(z) = \sum_{j=0}^{k} \alpha_j e^{jz} - z\beta_k e^{kz} - z\beta_{k+1} e^{(k+1)z},$$
$$R_{\rm est}(z) = \sum_{j=0}^{k} \sigma_j e^{jz} + z\sigma_{k+1} e^{kz} - z\sigma_{k+2} e^{(k+1)z}.$$
11

corresponding to  $le(t_n)$  and  $est(t_n)$ . To assess the quality of  $est(t_n)$  for large step sizes, we examine the ratio

$$r(z) = \frac{R_{\rm est}(z)}{R_{\rm le}(z)}.$$
(5.5)

We observe that the ratio (5.5) behaves in the following way:

$$r(z) \sim \frac{\sigma_0}{\alpha_0}, \quad |z| \to \infty, \quad \operatorname{Re}(z) < 0,$$

and this behaviour would suggest that the original estimate  $est(t_n)$  can be used for all the values of the stepsize. However, it is important to observe that the denominator appearing in the above expression could be quite small and, as a consequence, the ratio r(z) results to be very large and, therefore, the error estimate  $est(t_n)$  would not be reliable at all. To compensate for this, Shampine and Baca proposed in [14], in the context of RK methods, premultiplying  $est(t_n)$  by the so-called *filter matrix*,

$$(I-h\mathbf{J}(t_n))^{-1}$$

where  $\mathbf{J}(t_n)$  is an approximation to the Jacobian matrix of the problem (1.1) at the point  $t_n$ . This choice is suitable to damp the large, stiff error components. As observed in [14], the improved error estimator does not alter the behaviour for small h but it corrects the behaviour of the estimate for large values of h.

#### 6. Concluding remarks and future work

We have analyzed modified extended BDF of Cash [1, 2] in the framework of GLMs for ODEs. This analysis leads to the new classes of perturbed MEBDF methods of the same order, which have better stability properties than the MEBDF formulas for k = 4, 5, 6, 7, and 8. The resulting methods are  $A(\alpha)$ -stable with larger angles  $\alpha$  of stability. The improved stability properties were then confirmed by some numerical experiments. The future work will involve the incorporation of these methods into a variable stepsize variable order software for stiff systems of ODEs, by employing the error estimate provided in Section 5 and suitably extending the results obtained in [5, 6, 9].

Acknowledgements. The results reported in this paper were obtained during the visit of the third author to the University of Naples and University of Salerno in May 2009, March 2010 and May 2011. This author wishes to express his gratitude to Giuseppe Izzo, Elvira Russo and Beatrice Paternoster for making these visits possible.
